

# Measures of Association

## Association

**Statistical dependence between two or more events, characteristics, or variables**

**An association is present when the probability of occurrence of an event or characteristic, or the quantity of a variable, depends upon the occurrence of one or more other characteristics, or the quantity of one or more variables**

## What is RISK?

## What is RISK?

**probability of developing a condition  
over a defined period of time**

**# of people developing disease in time period**

**# of disease-free people at start of period**

**# of people developing TB in 5 years**

**# of people free of TB at start of 5 yr period**

## 1-year follow-up for the development of CHD

		CHD		Total
		+	-	
Smoking	+	84	2916	3000
	-	87	4913	5000

Incidence in exposed<sup>+</sup> =  $84/3000 = 28.0/1000$

Incidence in exposed<sup>-</sup> =  $87/5000 = 17.4/1000$

		CHD		Total
		+	-	
Smoking	+	84	2916	3000
	-	87	4913	5000

### Risk Difference/Attributable Risk

Incidence in exposed<sup>+</sup> =  $84/3000 = 28.0/1000$

Incidence in exposed<sup>-</sup> =  $87/5000 = 17.4/1000$

$$\mathbf{RD = 28.0 - 17.4 = 10.6/1000}$$

Among every 1000 smokers, 10.6 more cases of CHD develop than among 1000 non-smokers

## Risk Difference

- $RD > 0$  = positive association
- $RD = 0$  = no association
- $RD < 0$  = negative association

## Relative Risk

Probability of developing  
disease if risk factor is present

---

Probability of developing  
disease if risk factor is absent

Incidence of stroke in hypertensives  
Incidence of stroke in normotensives

		CHD		Total
		+	-	
Smoking	+	84	2916	3000
	-	87	4913	5000

## Relative Risk or Risk Ratio

Incidence in exposed<sup>+</sup> =  $84/3000 = 28.0/1000$

Incidence in exposed<sup>-</sup> =  $87/5000 = 17.4/1000$

$$RR = 28.0 \div 17.4 = 1.61$$

Risk for CHD among smokers is 1.6 times higher than among non-smokers

## Relative Risk

- $RR > 1$  = positive association
- $RR = 1$  = no association
- $RR < 1$  = negative association

**RR tells us about the strength of association between exposure and outcome but not about the magnitude of absolute risk (incidence)**

**Odds:**

- The ratio of the probability of occurrence of an event to that of

**Odds Ratio (or Relative Odds)**

- The ratio of the probability that something will occur, to the probability that it will not occur (Abramson, MSoD)

**“Odds is understood intuitively only by statisticians and professional gamblers”**

## **Odds Ratio (OR)**

**outcome**

**exposure**

<b>a</b>	<b>b</b>
<b>c</b>	<b>d</b>

## Odds Ratio (OR)

	<b>outcome</b>	
	<b>a</b>	<b>b</b>
<b>exposure</b>	<b>c</b>	<b>d</b>

## Odds Ratio (OR)

	<b>outcome</b>	
	<b>a</b>	<b>b</b>
<b>exposure</b>	<b>c</b>	<b>d</b>

### Prospective study (Disease OR)

Ratio of odds of outcome in exposed (a/b) to the odds of outcome in the unexposed (c/d):

$$\frac{a/b}{c/d} = \frac{ad}{bc}$$

		CHD		Total
		+	-	
Smoking	+	84	2916	3000
	-	87	4913	5000

## Odds Ratio

odds in exposed<sup>+</sup> =  $84/2916 = 28.8/1000$

odds in exposed<sup>-</sup> =  $87/4913 = 17.7/1000$

$$OR = 28.8 \div 17.7 = 1.63$$

ODDS for CHD among smokers is 1.63 times higher than among non-smokers

## Odds Ratio

- $OR > 1$  = positive association
- $OR = 1$  = no association
- $OR < 1$  = negative association

## OR $\cong$ RR when...

1. Outcome is rare because then:

$$b \cong (a + b) \text{ and } d \cong (c + d)$$

2. Cases are representative of all cases in the population re. exposure history

3. Controls representative of all non-cases in the population re. exposure history

	<b>outcome</b>		
<b>exposure</b>	<b>a</b>	<b>b</b>	<b>a+b</b>
	<b>c</b>	<b>d</b>	<b>c+d</b>

## OR in a retrospective study

	outcome	
exposure	a	b
	c	d

## Odds Ratio (OR)

	outcome	
exposure	a	b
	c	d

	<b>outcome</b>	
<b>exposure</b>	<b>a</b>	<b>b</b>
	<b>c</b>	<b>d</b>

**Retrospective study (Exposure OR):**

**Ratio of odds of exposure in cases (a/c) to the odds of exposure in controls (b/d):**

$$\frac{a/c}{b/d} = \frac{ad}{bc}$$

## RR & OR

- **OR is a useful measure of association in and of itself, in both case-control and prospective studies**
- **In a cohort study, RR can be calculated directly**
- **In a case-control study, RR cannot be calculated directly, so OR is used as an estimate of RR when the risk of disease is low**

## Advantages of Odds Ratio

- **Suitable for case-control studies**
- **Identical in both directions**
- **Basis for logistic regression analyses**

Now you try it!

History of sexual abuse	Suicide attempted	
	Yes	No
Yes	14	9
No	49	149

Deykin & Buka (1994) AJPH 84:634-9

History of sexual abuse	Suicide attempted		Total
	Yes	No	
Yes	14	9	23
No	49	149	198

$$R_{\text{exp}+} = 14/23 = 60.9\%$$

$$R_{\text{exp}-} = 49/198 = 24.7\%$$

$$RR = 60.9/24.7 = 2.46$$

History of sexual abuse	Suicide attempted		Total
	Yes	No	
Yes	14	9	23
No	49	149	198

$$RR = \frac{14/23}{49/198} = 2.46$$

History of sexual abuse	Suicide attempted	
	Yes	No
Yes	14	9
No	49	149

$$OR = \frac{14/9}{49/149} = 4.73$$

**Question:**  
**Why do the OR and RR differ?**

**Answer:**  
**high incidence**  
**(61% in exposed, 25% in unexposed)**  
**therefore  $b \neq a + b$  and  $d \neq c + d$**
